Vultr Agent Rush · Blast Radius Zero

FOR SHOP OPERATORS, BOOKKEEPERS AND TEAMS HANDLING BULK UPDATES

Check the next import. Undo the bad one.

You meant to update prices. The file also clears a field or resets a payment.
Catch that before import. Recover exact damaged values when a mistake gets through.

Before

Review and test the exact updates you want to import

After

Restore damaged cells while keeping newer work

Every time

Use the same check before the next bulk update

Shopify has already documented this problem: CSV imports cannot be canceled once started, and included blank fields can overwrite values.

BEFORE AN IMPORT · A RECURRING CHECK FOR THE PERSON RESPONSIBLE FOR UPDATES

You asked for new prices. Keep the other values.

1. Bring two CSVs

Today’s export and your proposed import are inspected in **separate gVisor containers on Vultr**.

2. Say what should change

Choose the intended fields and **a numeric change limit**, such as 25% for prices.

3. Hold mistakes out

Blank overwrites, unexpected fields, large price changes and **unknown IDs stay out**.

4. Approve exact cells

Review every included update. **Both files, your rules and exact selection** are bound to approval.

5. Execute the import

Build the approved CSV and **apply it to a disposable copy** using updates to existing records by ID.

6. Check and download

Fresh workers inspect both outputs. **Every approved and protected value** must match before download.

Executed example: 22 ordinary price updates included. 26 unwanted cell changes and one unknown ID excluded. All 24 records and payment statuses retained. Fixed preflight checks use no model calls.

Download the approved import, its resulting export, complete changes and checks

Recheck if operational data changes

AFTER A MISTAKE · REAL AI INVESTIGATION AND RECOVERY ON VULTR

The agent investigates. You approve the repair.

1. Inspect versions

Bring the good copy, incident checkpoint and today's file. **Trusted gVisor workers** read each version.

2. Investigate the mistake

Vultr Inference writes diagnostic code that actually compares the three copies in its own sandbox.

3. Protect later edits

The controller checks the proposal. **Observed overlaps stay unchanged**. You approve individual cells.

4. Write the recovery

A second Vultr call writes the exact repair. Generated code receives the cell mask, not acceptance answers.

5. Run on copies

The repair executes in **another gVisor container**. Your originals stay unchanged.

6. Verify every value

A fresh worker reads the result. The controller verifies **approved cells, protected values and cleanup**.

Executed recovery: 117 prices restored; all 127 invoices kept, including seven newer records, twenty payment updates and three prices edited again afterward. CSV and SQLite are supported.

At most two model calls · File contents and extracted record values stay outside inference

Checkpoint protects observed later edits

◀◀ rewind

CONTAINED EXECUTION AND A PRACTICAL REASON TO COME BACK

A result you can check. A reason to use it again.

```
def recover(a, b, c, d):
    while True:
        pass
```

2 seconds

Separate runaway-code probe on Vultr.
Deadline enforced. Container removal confirmed.

Why a business would pay

Someone has to check every price list or finance import and clean up mistakes afterward. That takes time and can affect sales or reconciliation.

- ✓ Check the next bulk update before import
- ✓ Keep unintended edits out
- ✓ Recover exact mistakes and keep newer work
- ✓ Review the approved changes and evidence

A team subscription for recurring checks and recovery is the natural commercial model. The public app is free to try.

gVisor · no network · read-only inputs · nonroot
Every data check and every container’s removal must pass before download.
